0. In the problem 1 below you would need to evaluate a couple of integrals of the form
\[ \int dx f(x) \times \exp(-Ag(x)) \] (1)
in the \( A \to \infty \) limit. The best way to obtain the asymptotic behavior of such integrals over real or complex variables is the saddle-point method (AKA the mountain-pass method). If you are not familiar with this method, read my notes. Those notes were originally written for a QM class, so they include the Airy function example and the relation of the Airy functions to the WKB approximation. You do not need the WKB or the Airy functions for this homework, just the saddle-point method itself, so focus on the first 6 pages of my notes, the rest is optional.

1. In this problem we shall see that the quantum mechanics of a single relativistic particle — or any fixed number of relativistic particles — violates relativistic causality by allowing the particles to move faster than light.

Indeed, consider a single free relativistic spinless particle with Hamiltonian
\[ \hat{H} = +\sqrt{M^2 + \hat{P}^2} \] (2)
in the \( c = \hbar = 1 \) units. By general rules of quantum mechanics, the amplitude \( U(x \to y) \) for this particle to propagate from point \( x \) at time \( x^0 \) to point \( y \) at time \( y^0 \) obtains from the Hamiltonian (2) as
\[ U(x \to y) = \langle y, y^0 | x, x^0 \rangle^{\text{Heisenberg}} = \langle y | \exp(-i(y^0 - x^0)\hat{H}) | x \rangle^{\text{Schroedinger}}. \] (3)

(a) Use momentum basis for the Hamiltonian (2) to evaluate the coordinate-basis evolution kernel (3) as
\[ U(x \to y) = \int \frac{d^3k}{(2\pi)^3} \exp\left(ik \cdot (y - x) - i\omega(k) \times (y^0 - x^0)\right) = 2i \frac{\partial}{\partial y^0} D(y - x) \] (4)
where \( \omega(k) = \sqrt{M^2 + k^2} \), then reduce the momentum integral to a one-dimensional
integral

\[ U(x \to y) = \frac{-i}{4\pi^2 r} \int_{-\infty}^{+\infty} dk \, k \exp(irk - it\omega(k)) \]  

(5)

where \( r = |y - x| \) and \( t = y^0 - x^0 \).

(b) Take the limit \( t \to +\infty \), \( r \to \infty \) while the ratio \( r/t \) stays fixed. Specifically, let \( (r/t) < 1 \) so we stay inside the future light cone.

Show that in this limit, the evolution kernel (5) becomes

\[ U(x \to y) \approx \frac{(-iM)^{3/2}}{4\pi^{3/2}} \frac{t}{(t^2 - r^2)^{5/4}} \times \exp(-iM\sqrt{t^2 - r^2}). \]  

(6)

Hint: Use the saddle point method to evaluate the integral (5).

(c) Finally, take a similar limit but go outside the light cone, thus fixed \( (r/t) > 1 \) while \( r, t \to +\infty \). Show that in this limit, the kernel becomes

\[ U(x \to y) \approx \frac{iM^{3/2}}{4\pi^{3/2}} \frac{t}{(r^2 - t^2)^{5/4}} \times \exp(-M\sqrt{r^2 - t^2}). \]  

(7)

Hint: again, use the saddle point method.

Eq. (7) shows that the kernel diminishes exponentially outside the light cone, but it does not vanish! Thus, given a particle localized at point \( x \) at the time \( x^0 \), at a later time \( y^0 = x^0 + t \) the wave function is mostly limited to the future light cone \( r < t \), but there is an exponential tail outside the light cone. In other words, the probability of superluminal motion is exponentially small but non-zero.

Obviously, such superluminal propagation cannot be allowed in a consistently relativistic theory. And that’s why relativistic quantum mechanics of a single particle is inconsistent. Likewise, relativistic quantum mechanics of any fixed number of particles does not work, except as an approximation.

In the quantum field theory, this paradox is resolved by allowing for creation and annihilation of particles. Quantum field operators acting at points \( x \) and \( y \) outside each others’ future lightcones can either create a particle at \( x \) and then annihilate it at \( y \), or else annihilate it at \( y \) and then create it at \( x \). I will show in class that the two effects precisely
cancel each other, so altogether there is no propagation outside the light cone. That’s how relativistic QFT is perfectly causal while the relativistic QM is not.

2. The rest of this homework is about the quantum massive vector field $A^\mu(x)$ and its expansion into creation and annihilation operators. The massive vector field has appeared in two previous homeworks: in set#1 you’ve derived its equation of motion from the Lagrangian, while in set#3 you’ve developed the Hamiltonian formalism and quantized the field. For the present exercise you will need the equal-times commutation relations of the quantum fields,

$$[\hat{A}^i(x), \hat{A}^j(y)] = 0, \quad [\hat{E}^i(x), \hat{E}^j(y)] = 0, \quad [\hat{A}^i(x), \hat{E}^j(y)] = -i\delta^{ij}\delta^3(x - y)$$

(in $\hbar = 1, c = 1$ units), the Hamiltonian operator

$$\hat{H} = \int d^3x \left( \frac{1}{2} \hat{E}^2 + \frac{(\nabla \cdot \hat{E})^2}{2m^2} + \frac{1}{2} (\nabla \times \hat{A})^2 + \frac{1}{2} m^2 \hat{A}^2 \right).$$

for the free fields (i.e., for $\hat{J}^\mu(x) \equiv 0$), and the operatorial identity

$$\hat{A}^0(x) = -\frac{\nabla \cdot \hat{E}(x)}{m^2}$$

(again, for $\hat{J}^0(x) \equiv 0$).

In general, a QFT has a creation operator $\hat{a}^\dagger_{k,\lambda}$ and an annihilation operator $\hat{a}_{k,\lambda}$ for each plane wave with momentum $k$ and polarization $\lambda$. The massive vector fields have 3 independent polarizations corresponding to 3 orthogonal unit 3–vectors. One may use any basis of 3 such vectors $e_\lambda(k)$, and it’s often convenient to make them $k$–dependent and complex; in the complex case, orthogonality+unit length mean

$$e_\lambda(k) \cdot e^*_\lambda(k) = \delta_{\lambda,\lambda'}.$$ 

Of particular convenience is the helicity basis of eigenvectors of the vector product $ik \times$, namely

$$ik \times e_\lambda(k) = \lambda |k| e_\lambda(k), \quad \lambda = -1, 0, +1.$$
By convention, the phases of the complex helicity eigenvectors are chosen such that
\[ e_0(k) = \frac{k}{|k|}, \quad e^*_\pm(k) = -e_{\mp 1}(k), \quad e_\lambda(-k) = -e^*_\lambda(+k), \]  
for example, for \( k \) pointing in the positive \( z \) direction
\[ e_{+1}(k) = \frac{1}{\sqrt{2}} (1, +i, 0), \quad e_{-1}(k) = \frac{1}{\sqrt{2}} (-1, +i, 0), \quad e_0(k) = (0, 0, 1). \]

As a first step towards constructing the \( \hat{a}_{k,\lambda} \) and \( \hat{a}^\dagger_{k,\lambda} \) operators, we Fourier transform the vector fields \( \hat{A}(x) \) and \( \hat{E}(x) \) and then decompose the vectors \( \hat{A}_k \) and \( \hat{E}_k \) into helicity components,
\[ \hat{A}(x) = \int \frac{d^3k}{(2\pi)^3} \sum_\lambda e^{ikx} e_\lambda(k) \hat{A}_{k,\lambda}, \quad \hat{A}_{k,\lambda} = \int d^3x e^{-ikx} e^*_\lambda(k) \cdot \hat{A}(x), \]
\[ \hat{E}(x) = \int \frac{d^3k}{(2\pi)^3} \sum_\lambda e^{ikx} e_\lambda(k) \hat{E}_{k,\lambda}, \quad \hat{E}_{k,\lambda} = \int d^3x e^{-ikx} e^*_\lambda(k) \cdot \hat{E}(x). \]  

(a) Show that \( \hat{A}^\dagger_{k,\lambda} = -\hat{A}_{-k,\lambda}, \hat{E}^\dagger_{k,\lambda} = -\hat{E}_{-k,\lambda} \), and derive the equal-time commutation relations for the \( \hat{A}_{k,\lambda} \) and \( \hat{E}_{k,\lambda} \) operators.

(b) Show that
\[ \hat{H} = \int \frac{d^3k}{(2\pi)^3} \sum_\lambda \left( \frac{C_{k,\lambda}}{2} \hat{E}^\dagger_{k,\lambda} \hat{E}_{k,\lambda} + \frac{\omega_k^2}{2C_{k,\lambda}} \hat{A}^\dagger_{k,\lambda} \hat{A}_{k,\lambda} \right) \]
where \( \omega_k = \sqrt{k^2 + m^2} \),  
and \( C_{k,\lambda} = \begin{cases} \omega_k^2/m^2 & \text{for } \lambda = 0, \\ 1 & \text{for } \lambda = \pm 1. \end{cases} \)  

(c) Define creation and annihilation operators according to
\[ \hat{a}_{k,\lambda} = \frac{\omega_k \hat{A}_{k,\lambda} - iC_{k,\lambda} \hat{E}_{k,\lambda}}{\sqrt{C_{k,\lambda}}}, \quad \hat{a}^\dagger_{k,\lambda} = \frac{\omega_k \hat{A}^\dagger_{k,\lambda} + iC_{k,\lambda} \hat{E}^\dagger_{k,\lambda}}{\sqrt{C_{k,\lambda}}}, \]
and verify that they satisfy equal-time bosonic commutation relations (relativistically normalized).
(d) Show that

\[ \hat{H} = \int \frac{d^3 \mathbf{k}}{(2\pi)^3 2\omega_k} \sum_\lambda \omega_k \hat{a}_{k,\lambda}^\dagger \hat{a}_{k,\lambda} + \text{const.} \] (18)

(e) Next, consider the time dependence of the free vector field in the Heisenberg picture. Show that

\[ \hat{A}(\mathbf{x},t) = \int \frac{d^3 \mathbf{k}}{(2\pi)^3 2\omega_k} \sum_\lambda \sqrt{C_{k,\lambda}} \left( e^{-ikx} \mathbf{e}_\lambda(\mathbf{k}) \hat{a}_{k,\lambda}(0) + e^{ikx} \mathbf{e}_\lambda^*(\mathbf{k}) \hat{a}_{k,\lambda}^\dagger(0) \right)_{k^0 = +\omega_k}. \] (19)

(f) Write down similar expansion for the electric field \( \hat{E}(\mathbf{x},t) \) and the scalar potential \( \hat{A}^0(\mathbf{x},t) \); use eq. (10) for the latter.

(g) Combine the results of parts (e) and (f) into a relativistic formula for the 4–vector field \( \hat{A}^\mu(\mathbf{x}) \), namely

\[ \hat{A}_{\mu}(\mathbf{x}) = \int \frac{d^3 \mathbf{k}}{(2\pi)^3 2\omega_k} \sum_\lambda \left( e^{-ikx} f_{\mu}(\mathbf{k},\lambda) \hat{a}_{k,\lambda}(0) + e^{ikx} f_{\mu}^*(\mathbf{k},\lambda) \hat{a}_{k,\lambda}^\dagger(0) \right)_{k^0 = +\omega_k} \] (20)

where the 4–vectors \( f_{\mu}(\mathbf{k},\lambda) \) obtain by Lorentz boosting of purely-spatial polarization vectors \( \mathbf{e}_\lambda(\mathbf{k}) \) into the moving particle’s frame. Specifically,

\[ f_{\mu}(\mathbf{k},\lambda) = \begin{cases} (0, \mathbf{e}_\lambda(\mathbf{k})) & \text{for } \lambda = \pm 1, \\ \left( \frac{|\mathbf{k}|}{m}, \omega_k, \frac{\mathbf{k}}{|\mathbf{k}|} \right) & \text{for } \lambda = 0, \end{cases} \] (21)

and they satisfy

\[ k_\mu f_{k,\lambda}^\mu = 0, \quad f_{k,\lambda}^\mu \left( f_{k,\lambda'}^\ast \right)_\mu = -\delta_{\lambda,\lambda'}. \] (22)

(h) Finally, verify that the quantum vector field (20) satisfies the free equations of motion

\[ \partial_\mu \hat{A}^\mu(x) = 0 \quad \text{and} \quad (\partial^2 + m^2)\hat{A}^\mu(x) = 0; \] moreover, each mode in the expansion (20) satisfies the equations of motions without any help from the other modes.
3. The last problem concerns the Feynman propagator for the massive vector field. I recommend you do this problem after I explain the scalar field’s Feynman propagator in class on Thursday 10/1.

(a) First, a lemma: Show that
\[ \sum_\lambda f^\mu(k, \lambda) f^{\nu*}(k, \lambda) = -g^{\mu\nu} + \frac{k^\mu k^\nu}{m^2}. \] (23)

(b) Next, calculate the “vacuum sandwich” of two vector fields and show that
\[ \langle 0 | \hat{A}^\mu(x) \hat{A}^\nu(y) | 0 \rangle = \int \frac{d^3k}{(2\pi)^3} \frac{1}{2\omega_k} \left[ \left( -g^{\mu\nu} + \frac{k^\mu k^\nu}{m^2} \right) e^{-ik(x-y)} \right] k^0 = \omega_k \] (24)
\[ = \left( -g^{\mu\nu} - \frac{\partial^\mu \partial^\nu}{m^2} \right) D(x - y). \]

(c) And now, the Feynman propagator: Show that
\[ G_{F}^{\mu\nu} \equiv \langle 0| T^* \hat{A}^\mu(x) \hat{A}^\nu(y) | 0 \rangle = \left( -g^{\mu\nu} - \frac{\partial^\mu \partial^\nu}{m^2} \right) G_{F}^{\text{scalar}}(x - y) \] (25)
\[ = \int \frac{d^4k}{(2\pi)^4} \left( -g^{\mu\nu} + \frac{k^\mu k^\nu}{m^2} \right) \frac{ie^{-ik(x-y)}}{k^2 - m^2 + i0} \]
where
\[ T^* \hat{A}^\mu(x) \hat{A}^\nu(y) = T \hat{A}^\mu(x) \hat{A}^\nu(y) + \frac{i}{m^2} \delta^{\mu0} \delta^{\nu0} \delta^{(4)}(x - y), \] (26)
is the modified time-ordered product of the vector fields. The purpose of this modification\(^*\) is to absorb the \(\delta^{(4)}(x - y)\) stemming from the \(\partial_0 \partial_0 G_F(x - y)\).

(d) Finally, write the classical action for the free vector field as
\[ S = \frac{1}{2} \int d^4x \; A_\mu(x) D^{\mu\nu} A_\nu(x) \] (27)
where \(D^{\mu\nu}\) is a differential operator and show that the Feynman propagator (25) is a Green’s function of this operator,
\[ D_x^{\mu\nu} G_{F\nu\lambda} = +i\delta^\mu_\lambda \delta^{(4)}(x - y). \] (28)
