EDDY CURRENTS, DIFFUSION, AND SKIN EFFECT

The magnetic field cannot instantly penetrate a conducting material, it has to diffuse in from the surface. The reason for this behavior are eddy currents due to EMF induced by the changing magnetic field; these currents in turn cause magnetic fields opposing the change of the original field.

To see how this works, consider a large piece of a uniform material of electric conductivity \( \sigma \) and magnetic permeability \( \mu \). There are several equations relating the electric field, the magnetic field, and the conduction current in this material:

the Ohm’s law

\[
\mathbf{J} = \sigma \mathbf{E}; \tag{1}
\]

the Ampere’s law*

\[
\nabla \times \mathbf{B} = \mu_0 \nabla \times \mathbf{H} = \mu_0 \mathbf{J}; \tag{2}
\]

and the Faraday’s law of induction for the fields

\[
\nabla \times \mathbf{E} = -\frac{\partial \mathbf{B}}{\partial t}. \tag{3}
\]

Combining these equations, we obtain

\[
\nabla \times \mathbf{B} = \mu_0 \mathbf{J} = \mu_0 \sigma \mathbf{E}, \tag{4}
\]

\[
\nabla \times (\nabla \times \mathbf{B}) = \mu_0 \sigma \nabla \times \mathbf{E} = -\mu_0 \sigma \frac{\partial \mathbf{B}}{\partial t}, \tag{5}
\]

\[
\nabla^2 \mathbf{B} = \nabla(\nabla \cdot \mathbf{B}) - \nabla \times (\nabla \times \mathbf{B}) = 0 + \mu_0 \sigma \frac{\partial \mathbf{B}}{\partial t}, \tag{6}
\]

* Strictly speaking, for the time-dependent field we should use the Maxwell–Ampere law which includes the displacement current \( \partial \mathbf{D}/\partial t \) in addition to the conduction current \( \mathbf{J} \). But in good conductors and less-than-optical frequencies the conduction current is so much stronger than the displacement current that the latter may be neglected.
and hence the *diffusion equation* for the magnetic field

\[ \frac{\partial}{\partial t} \mathbf{B}(\mathbf{x}, t) = \mathcal{D} \nabla^2 \mathbf{B}(\mathbf{x}, t) \]  

(7)

for the *diffusion coefficient*

\[ \mathcal{D} = \frac{1}{\mu_0 \sigma} = \frac{\rho}{\mu_0}. \]

(8)

The current density \( \mathbf{J}(\mathbf{x}, t) \) obeys a similar diffusion equation with the same diffusion coefficient \( \mathcal{D} \). Indeed, taking the curl of both sides of eq. (7), multiplying by \( \mu_0 \), and using the Ampere’s law, we obtain

\[ \frac{\partial}{\partial t} (\mu_0 \nabla \times \mathbf{B}) = \mu_0 \nabla \times \frac{\partial \mathbf{B}}{\partial t} = \mu_0 \nabla \times (\mathcal{D} \nabla^2 \mathbf{B}) = \mathcal{D} \nabla^2 (\mu_0 \nabla \times \mathbf{B}) \]

(9)

and hence

\[ \frac{\partial}{\partial t} \mathbf{J}(\mathbf{x}, t) = \mathcal{D} \nabla^2 \mathbf{J}(\mathbf{x}, t). \]

(10)

**Solving the Diffusion Equation: An Example**

As an example of magnetic diffusion, consider a solid metal cylinder surrounded by a solenoidal coil. When we turn on the current in the coil, the surface of the metal cylinder is suddenly exposed to the coil’s \( \mathbf{H} \) field parallel to the cylinder. But this field cannot instantly penetrate the cylinder; instead, it has to diffuse inward from the surface according to the diffusion equation (7). This means that at the moment the coil’s current \( I \) is turned on, we get an equal and opposite counter-current on the cylinder’s surface,

\[ \mathbf{J}(z, s, \phi) = -K \delta(s - R) \mathbf{n}_\phi \quad \text{for } K = \frac{IN}{L}, \]

(11)

but then this counter-current diffuses in towards the cylinder’s center, which allows the magnetic field to penetrate the surface and diffuse in:

\[ \text{for } t > 0, \quad \mathbf{J}(\mathbf{x}, t) = J(s, t) \mathbf{n}_\phi, \quad \mathbf{B}(\mathbf{x}, t) = B(s, t) \mathbf{n}_z \]

(12)

for some time-dependent radial profiles \( J(s, t) \) and \( B(s, t) \).
Alas, solving the diffusion equation for the time dependence of these radial profiles involves Bessel functions and their relatives, so let’s consider a simpler, one-dimensional example: An infinite slab of metal with a flat current sheet just above it:

In this picture the $x_1$ axis points down while the $x_2$ and $x_3$ axes are horizontal, the metal fills up the $x_1 > 0$ half space, and the current sheet carries a uniform current density in the $x_3$ direction. All by itself, this current would create a uniform magnetic field below the sheet in the $x_2$ direction, but the conduction current in the metal makes the problem much more interesting. Still, it’s a one-dimensional problem where the magnetic field and the current in the metal depend only on the $x_1$ coordinate but not the $x_2$ or the $x_3$. Also, in the metal the current always flows in the $\pm x_3$ direction while the $\mathbf{H}$ field points in the $\pm x_2$ direction, thus

$$
\mathbf{J}(\mathbf{x},t) = -J(x_1,t) \mathbf{n}_3, \quad \mathbf{H}(\mathbf{x},t) = H(x_1,t) \mathbf{n}_2.
$$

With these sign/direction conventions, the Ampere law becomes

$$
J(x_1,t) = -\frac{\partial H}{\partial x_1},
$$

so once we solve the 1D diffusion equation

$$
\frac{\partial J}{\partial t} = D \frac{\partial^2 J}{\partial x_1^2}
$$

3
for the current, the solution for the magnetic field obtains by integration

\[ H(x_1, t) = + \int_{x_1}^{\infty} J(x', t) \, dx'. \]  

(16)

Note: the upper limit in this formula follows from the asymptotic condition \( H = 0 \) infinitely deep inside the metal for any finite time \( t \).

The simplest way to solve the diffusion equation (15) is via the Fourier transform. First, to avoid problems with the abrupt discontinuity of the current at the metal’s edge \( x = 0 \), let’s formally continue the \( J(x_1) \) profile to negative \( x_1 \) by making it an even function of \( x_1 \) thus

\[ \tilde{J}(\pm x) = J(\pm x). \]  

(17)

Next we Fourier transform from \( x_1 \) to \( k \) for each time \( t \),

\[ \tilde{J}(x, t) = \int_{-\infty}^{+\infty} \frac{dk}{2\pi} e^{ikx} \times F(k, t), \]  

(18)

\[ F(k, t) = \int_{-\infty}^{+\infty} dx \, e^{-ikx} \times \tilde{J}(x, t) = \int_{0}^{\infty} dx \, (e^{-ikx} + e^{+ikx}) \times J(x, t). \]  

(19)

In terms of the \( F(x, t) \), the \( x \) derivative acts by multiplying by \( ik \), so the diffusion equation becomes

\[ \frac{\partial F}{\partial t} = -Dk^2 \times F(k, t). \]  

(20)

For each \( k \), this is a simple linear differential equation WRT time \( t \), whose solution is

\[ F(k, t) = F(k, 0) \times \exp(-Dk^2 \times t). \]  

(21)

Now let’s apply eqs.(18), (19), and (21) to the problem at hand.
Now suppose the current $K$ in the current sheet stays zero for a long while, and then abruptly turns on at $t = 0$ and then stays constant. This outside current suddenly creates a magnetic field $H_0$ just outside the metal, and since this field cannot instantly penetrate the metal, it has to be screened by the surface current in the metal itself. This means that at the initial time $t = 0$, $H(x_1)$ inside or near metal is given by the step function $H(x_1) = H_0 \Theta(-x_1)$, or rather

$$H(x_1) \approx H_0 \Theta(\epsilon - x_1) \tag{22}$$

for some microscopically small depth $\epsilon$ inside the metal. Consequently, the initial current in the metal is

$$\frac{\partial}{\partial t} = 0, \quad J(x_1, 0) = -\frac{\partial H}{\partial x_1} = +H_0 \delta(x_1 - \epsilon), \tag{23}$$

and according to eq. (19), the Fourier transform of this current is

$$F(k, 0) = \int_0^\infty dx \left(e^{-ikx} + e^{+ikx}\right) \times H_0 \delta(x - \epsilon) = 2H_0 \cos(k\epsilon) \approx \text{constant } 2H_0. \tag{24}$$

According to eq. (21), at later times $t > 0$ this transform becomes

$$F(k, t) = 2H_0 \times \exp(-Dk^2 \times t), \tag{25}$$

so Fourier transforming from $k$ back to $x_1$, we obtain the current profile

$$J(x_1, t) = \int \frac{dk}{2\pi} e^{ikx_1} \times 2H_0 \exp(-Dt \times k^2)$$

$$= \frac{H_0}{\pi} \int dk \exp \left(-Dt \left(k - \frac{ix_1}{2Dt}\right)^2 - \frac{x_1^2}{4Dt}\right)$$

$$= \frac{H_0}{\pi} \times \exp \left(-\frac{x_1^2}{4Dt}\right) \times \int d(k + \text{const}) \exp(-Dt(k + \text{const})^2) \tag{26}$$

$$= \frac{H_0}{\pi} \times \exp \left(-\frac{x_1^2}{4Dt}\right) \times \sqrt{\frac{\pi}{Dt}}$$

$$= \frac{2H_0}{\sqrt{4\pi Dt}} \times \exp \left(-\frac{x_1^2}{4Dt}\right).$$
This is a Gaussian profile of the form

\[ J(x_1, t) = \frac{2H_0}{\sqrt{\pi} a(t)} \times \exp \left( -\frac{x_1^2}{a^2(t)} \right) \]  \hspace{1cm} (27)

—or rather the \( x_1 > 0 \) half of the Gaussian profile, — whose width increases with time as

\[ a(t) = \sqrt{4D \times t} \]  \hspace{1cm} (28)

As to the magnetic field \( H(x_1, t) \), it obtains from integrating the Ampere’s law according to eq. (16):

\[ H(x_1, t) = \int_{x_1}^{\infty} J(x_1, t) = \frac{2H_0}{\sqrt{\pi} a(t)} \times \int_{x_1}^{\infty} \exp(-x'^2/a^2(t)) \, dx' = H_0 \times (1 - \text{erf}(x_1/a(t))) \]  \hspace{1cm} (29)

where \( \text{erf} \) is the error function of the Gaussian distribution.

**Skin Effect**

Now consider an AC current

\[ J(x, t) = \text{Re} \left( J(x) e^{-i\omega t} \right) \]  \hspace{1cm} (30)

flowing down a thick wire. For such an AC current, the diffusion equation (10) becomes

\[ \nabla^2 J(x) = \frac{1}{D} \frac{\partial J}{\partial t} = -i\omega J(x) \]  \hspace{1cm} (31)

Because of the imaginary coefficient on the RHS, all solutions to this equation are complex, which means that not only the amplitude but also the phase of the AC current vary from one point \( x \) to another.

For a round wire, the radial profile of an axially symmetric solution of eq. (31) involves Bessel functions of complex arguments, so its qualitative features are rather hard to extract. So let’s consider a wire which is so thick that near its surface it looks like an infinite half-space worth of metal, just like we had in the previous example. Again, we assume that the
current density \( J(x) = J(x_1) \mathbf{n}_3 \) depends only on the depth \( x_1 \), so eq. (31) becomes the 1D differential equation

\[
\frac{d^2 J}{dx_1^2} = -\frac{i\omega}{D} \times J(x_1).
\] (32)

The two independent solutions to this equation are

\[
J(x_1) \propto \exp(\pm \kappa x_1)
\] (33)

for

\[
\kappa = \sqrt{-\frac{i\omega}{D}} = \sqrt{\frac{\omega}{D}} \times \left( \sqrt{-i} = e^{-\pi i/4} = \frac{1 - i}{\sqrt{2}} \right).
\] (34)

The choice of the right solution follows from requiring the current density to vanish at infinite depth, \( J \to 0 \) for \( x_1 \to \infty \), and since \( \kappa \) has a positive real part,

\[
J(x_1) = J_0 \times \exp(-\kappa x_1),
\] (35)

so that its magnitude is decreases with depth as

\[
|J(x_1)| = |J_0| \times \exp(-\text{Re} \, \kappa \times x_1).
\] (36)

This decrease of the current’s amplitude with depth is called the **dred skin effect**: a high-frequency AC current flows only near the surface of the conductor. The **skin depth** — the effective depth through which the current flows — obtains as

\[
\delta = \frac{1}{\text{Re} \, \kappa} = \sqrt{\frac{2D}{\omega}} = \sqrt{\frac{2\mu\mu_0}{\rho\omega}}.
\] (37)

For example, for copper at room temperature \( \rho = 1.68 \cdot 10^{-8} \ \Omega/m \) and \( \mu \approx 1 \), hence

\[
\delta = \frac{65.2 \ \text{mm}}{\sqrt{f[\text{in Hz}]}}.
\] (38)

for the 60 Hz AC current in the power wires, this skin depth is 8.4 mm, but for the 700 MHz frequency used by many cellphones, the skin depth in a copper wire is only 2.5 microns.
In a round wire of radius $r_w$ much larger than the skin depth $\delta$, the AC currents flows mostly near the surface of the wire and decreases with depth in similarly to the current in the metal slab of our example,

$$J_z(s) \approx J_{\text{surface}} \times \exp \left( -\frac{(r_w - s)}{\delta} + i\frac{(r_w - s)}{\delta} \right).$$  \hspace{1cm} (39)$$

Because of this effect, the AC resistivity of the wire is

$$R_{\text{AC}} \approx \frac{\rho L}{2\pi r \delta},$$ \hspace{1cm} (40)$$

which is much larger than the DC resistance

$$R_{\text{DC}} = \frac{\rho L}{\pi r^2}.$$ \hspace{1cm} (41)$$
