Phase Space Factors

For quantum transitions to un-bound states — for example, an atom emitting a photon, or a radioactive decay, or scattering — which is a kind of unbound $\rightarrow$ unbound transition, — the transition rate is given by the Fermi’s golden rule:

$$\Gamma \equiv \frac{d\text{probability}}{d\text{time}} = \frac{2\pi\rho}{\hbar} \times \left|\langle\text{final} | \hat{T} | \text{initial}\rangle\right|^2$$  \hspace{1cm} (1)

where $\hat{T} = \hat{H}_{\text{perturbation}} + \text{higher order corrections}$, and $\rho$ is the density of final states,

$$\rho = \frac{dN_{\text{final states}}}{dE_{\text{final}}}.$$  \hspace{1cm} (2)

For an example, consider an atom emitting a photon of specific polarization $\lambda$. Using the large-box normalization for the photon’s states, we have

$$dN_{\text{final}} = \left(\frac{L}{2\pi}\right)^3 d^3k_\gamma = \frac{L^3}{(2\pi)^3} \times k^2_\gamma \, dk_\gamma \, d^2\Omega_\gamma$$  \hspace{1cm} (3)

while $dE_{\text{final}} = dE_\gamma = \hbar c \times dk_\gamma$, hence

$$\rho = L^3 \times \frac{k^2_\gamma}{(2\pi)^3\hbar c} \times d^2\Omega_\gamma.$$  \hspace{1cm} (4)

The $L^3$ factor here cancels against the $L^{-3/2}$ factor in the matrix element $\langle\text{atom'} + \gamma | \hat{T} | \text{atom}\rangle$ due to the photon’s wave function in the large-box normalization. As to the remaining $d^2\Omega_\gamma$ factor, we should integrate over it to get the total decay rate, or divide by it to get the partial emission rate $d\Gamma/d\Omega$ for the photons emitted in a particular direction, thus

$$\frac{d\Gamma(\lambda)}{d\Omega} = \frac{k^2}{(2\pi)^3\hbar c} \times L^3 \left|\langle\text{atom'} + \gamma(k,\lambda) | \hat{T} | \text{atom}\rangle\right|^2,$$

$$\Gamma_{\text{total}} = \int d\Omega \sum_\lambda \frac{k^2}{(2\pi)^3\hbar c} \times L^3 \left|\langle\text{atom'} + \gamma(k,\lambda) | \hat{T} | \text{atom}\rangle\right|^2.$$  \hspace{1cm} (5)

In relativistic normalization of quantum states and matrix elements, there are no $L^{-3/2}$ factors but instead there are $\sqrt{2E}$ factors for each final-state or initial state particle, and
they must be compensated by dividing the density of states \( \rho \) by the \( \Pi_i (2E_i) \). Also, we must allow for motion of all the final-state particles (i.e., both the photon and the recoiled atom) but impose the momentum conservation as a constraint. Thus, for a decay of 1 initial particle into \( n \) final particles,

\[
\Gamma = \frac{1}{2E_{\text{init}}} \int \frac{d^3 p_1'}{(2\pi)^3 2E_1'} \cdots \int \frac{d^3 p_n'}{(2\pi)^3 2E_n'} \left| \langle p_1', \ldots, p_n' | M | p_{\text{init}} \rangle \right|^2 \times (2\pi^4)\delta^{(4)}(p_1' + \cdots + p_n' - p_{\text{init}}),
\]

where the \( \delta \) function takes care of both momentum conservation and of the denominator \( dE_f \) in the density-of-states factor (2). Likewise, the transition rate for a generic \( 2 \rightarrow n \) scattering process is given by

\[
\Gamma = \frac{1}{2E_1 \times 2E_2} \int \frac{d^3 p_1'}{(2\pi)^3 2E_1'} \cdots \int \frac{d^3 p_n'}{(2\pi)^3 2E_n'} \left| \langle p_1', \ldots, p_n' | M | p_1, p_2 \rangle \right|^2 \times (2\pi^4)\delta^{(4)}(p_1' + \cdots + p_n' - p_1 - p_2).
\]

In terms of the scattering cross-section \( \sigma \), the rate (7) is \( \Gamma = \sigma \times \text{flux of initial particles} \). In the large-box normalization the flux is \( L^{-3} |v_1 - v_2| \), so in the continuum normalization it’s simply the relative speed \( |v_1 - v_2| \). Consequently, the total scattering cross-section is given by

\[
\sigma_{\text{tot}} = \frac{1}{4E_1 E_2 |v_1 - v_2|} \int \frac{d^3 p_1'}{(2\pi)^3 2E_1'} \cdots \int \frac{d^3 p_n'}{(2\pi)^3 2E_n'} \left| \langle p_1', \ldots, p_n' | M | p_1, p_2 \rangle \right|^2 \times (2\pi^4)\delta^{(4)}(p_1' + \cdots + p_n' - p_1 - p_2).
\]

In particle physics, all the factors in eqs (6) or (8) besides the matrix elements — as well as the integrals over such factors — are collectively called the phase space factors.

A note on Lorentz invariance of decay rates or cross-sections. The matrix elements \( \langle \text{final} | M | \text{initial} \rangle \) are Lorentz invariant, and so are all the integrals over the final-particles’ momenta and the \( \delta \)-functions. The only non-invariant factor in the decay-rate formula (6) is the pre-integral \( 1/E_{\text{init}} \), hence the decay rate of a moving particle is

\[
\Gamma(\text{moving}) = \Gamma(\text{rest frame}) \times \frac{M}{E}
\]

where \( M/E \) is precisely the time dilation factor in the moving frame.
As to the scattering cross-section, it should be invariant under Lorentz boosts along the initial axis of scattering, thus the same cross-section in any frame where \( p_1 \parallel p_2 \). This includes the lab frame where one of the two particles is initially at rest, the center-of-mass frame where \( p_1 + p_2 = 0 \), and any other frame where the two particles collide head-on. And indeed, the pre-integral factor in eq. (8) for the cross-section

\[
\frac{1}{4E_1E_2|v_1 - v_2|} = \frac{1}{4|E_1p_2 - E_2p_1|}
\]

is invariant under Lorentz boosts along the scattering axis.

Let’s simplify eq. (8) for a 2 particle \( \rightarrow \) 2 particle scattering process in the center-of-mass frame where \( p_1 + p_2 = 0 \). In this frame, the pre-exponential factor (10) becomes

\[
\frac{1}{4|p| \times (E_1 + E_2)}
\]

while the remaining phase space factors amount to

\[
P_{\text{int}} = \int \frac{d^3p_1'}{(2\pi)^3 2E_1'} \int \frac{d^3p_2'}{(2\pi)^3 2E_2'} (2\pi)^4 \delta(3)(p_1' + p_2') \delta(E_1' + E_2' - E_{\text{net}})
\]

\[
= \int \frac{d^3p_1'}{(2\pi)^3 \times 2E_1' \times 2E_2'} (2\pi)^4 \delta(E_1'(p_1') + E_2'(-p_1') - E_{\text{net}})
\]

\[
= \int d^2\Omega_{p'} \times \int_{0}^{\infty} dp' \frac{p'^2}{16\pi^2E_1'E_2'} \times \delta(E_1' + E_2' - E_{\text{tot}})
\]

\[
= \int d^2\Omega_{p'} \left[ \frac{p'^2}{16\pi^2E_1'E_2'} \right] \frac{d(E_1' + E_2')}{dp'} \bigg|_{E_1' + E_2' = E_{\text{tot}}}. \tag{12}
\]

On the last 3 lines here \( E_1' = E_1'(p_1') = \sqrt{p'^2 + m_1'^2} \) while \( E_2' = E_2'(p_2' = -p_1') = \sqrt{p'^2 + m_2'^2} \). Consequently,

\[
\frac{dE_1'}{dp'} = \frac{p'}{E_1'}, \quad \frac{dE_2'}{dp'} = \frac{p'}{E_2'}, \tag{13}
\]

hence

\[
\frac{d(E_1' + E_2')}{dp'} = \frac{p'}{E_1'} + \frac{p'}{E_2'} = \frac{p'}{E_1'E_2'} \times (E_2' + E_1' = E_{\text{tot}}), \tag{14}
\]
and therefore
\[ P_{\text{int}} = \frac{1}{16\pi^2} \times \frac{p'}{E_{\text{tot}}} \times \int d^2 \Omega_{p'}. \] (15)

Including the pre-integral factor (11), we arrive at the net phase space factor
\[ P = \frac{p'}{p} \times \frac{1}{64\pi^2 E_{\text{tot}}^2} \times \int d^2 \Omega_{p'}. \] (16)

The matrix element \( \mathcal{M} \) for the scattering should be put inside the direction-angle integral in this phase-space formula. Thus, the total scattering cross-section is
\[ \sigma_{\text{tot}}(1 + 2 \rightarrow 1' + 2') = \frac{p'}{p} \times \frac{1}{64\pi^2 E_{\text{cm}}^2} \times \int d^2 \Omega \left| \langle p_1' + p_2' | \mathcal{M} | p_1 + p_2 \rangle \right|^2, \] (17)

while the partial cross-section for scattering in a particular direction is
\[ \frac{d\sigma(1 + 2 \rightarrow 1' + 2')}{d\Omega_{\text{cm}}} = \frac{p'}{p} \times \frac{1}{64\pi^2 E_{\text{cm}}^2} \times \left| \langle p_1' + p_2' | \mathcal{M} | p_1 + p_2 \rangle \right|^2. \] (18)

Note: the total cross-section is the same in frames where the initial momenta are collinear, but in the partial cross-section, \( d\Omega \) depends on the frame of reference, so eq. (18) applies only in the center-of-mass frame. Also, the \( E_{\text{cm}} \) factor in denominators of both formulae stands for the net energy in the center-of-mass frame. In frame-independent terms,
\[ E_{\text{cm}}^2 = (p_1 + p_2)^2 = (p_1' + p_2')^2 = s. \] (19)

Finally, let me write down the phase-space factor for a 2-body decay (1 particle \( \rightarrow \) 2 particles) in the rest frame of the initial particle. The under-the-integral factors for such a decay are the same as in eq. (15) for a 2 \( \rightarrow \) 2 scattering, but the pre-integral factor is \( 1/2M_{\text{init}} \) instead of the (11), thus
\[ P = \frac{p'}{32\pi^2 M^2}, \] (20)

meaning
\[ \frac{d\Gamma(0 \rightarrow 1' + 2')}{d\Omega} = \frac{p'}{32\pi^2 M^2} \times \left| \langle p_1' + p_2' | \mathcal{M} | p_0 \rangle \right|^2, \] (21)

\[ \Gamma(0 \rightarrow 1' + 2') = \frac{p'}{32\pi^2 M^2} \times \int d^2 \Omega \left| \langle p_1' + p_2' | \mathcal{M} | p_0 \rangle \right|^2. \] (22)
